

Controlled experiment: separate conditioning, density, and decoder sensitivity

Fixed throughout: E / D weights + normalization + graph hierarchy
Condition c = geometry + thickness + recorded B.C.; vary only the random realization

0. Validate paths
GT / posterior / prior
checkpoint parity

1. Fit one condition
Can a prior reproduce
its latent cloud?

2. Compare families
FM / EDM / implicit
same conditioner

3. Change one factor
graph-token context
then field score

Split A: new realizations at known conditions
Split B: held-out geometries / thickness ranges
No test targets in a training latent bank

Measure joint latent + field distributions
PV / tails / spatial dependence / B.C. residuals*
Report three seeds, time and denoiser NFE

Proposed procedure, not completed training. * B.C. residuals require verified physical constraints.
